⑲ Control system for a sample preparation system.

⑲ There is disclosed herein a system for controlling an electromechanical system comprised of a number of electromechanical devices (e.g., 30, 32, 34, 36, 38, 40, etc.) such as solenoid operated valves, motor, relays and other devices. The control system is comprised of a central processing unit (20) and control software plus suitable interface circuitry to convert the digital data from the central processing unit into suitable control signals to operate the electromechanical devices. The control software allows users to either select preprogrammed sequences of commands to be executed by the computer or to program unique sequence at either of two levels of complexity. User access privileges may be defined by the system manager such that certain users may not be allowed to program their own sequences, while other users may be allowed to program their own sequences only on the first level of complexity but not the second, while a third group of users may be allowed to program on either of the programming levels or to run the preprogrammed sequence as defined by the system manager. The two levels of programming complexity are a high level and an expert level where the command set on

the high level consists of a plurality of commands each of which represents a macro. A macro is a collection of more detailed commands from the expert level each of which represents a single operation to be performed or a very small group of operations by the electromechanical devices being controlled. Collections of these commands from the expert level are then put together in prearranged sequences to define predetermined functions of the system which may be performed by the single high level command representing that macro. The command set on the expert level is therefore comprised of commands which define single operation such as valve openings and closures or relay openings or closures or the turning on of a motor or the turning off of a motor.

FIG. 2

CONTROL SYSTEM FOR A SAMPLE PREPARATION SYSTEM

Background of the Invention

The invention pertains to the field of sample preparation systems, and more particularly, to the field of control systems for automated sample preparation systems.

In many industrial production facilities and laboratories, there is a need to assay sample chemicals being prepared, analyzed or otherwise processed. Such samples can come in many different forms. For example, they may be solid, liquid, two phase liquid or liquid-solid, and may or may not be highly viscous. Many types of assay systems require liquid samples of known viscosity and concentration. An example would be a liquid chromatography system.

Obviously, there is a need for systems which can prepare many different types of samples for assay by such machines. Preferably such systems are automatic in the sense that after the user defines the type of sample preparation needed, the system automatically carries out this processing on samples until told to stop or until the sample preparation runs out of samples.

Because of the many different types of sample formats and because of the many different types of sample preparation processes which exist for various types of assays, there is a need for flexibility and programmability in a control system for an automated sample preparation system. The user must be provided the facility with which the particular types of samples he or she intends to process may be prepared in a process for which the steps and sequence of steps are defined by the user. In this way the user can tailor the automatic sample preparation system for use in the environment peculiar to that particular user.

Prior art automatic sample preparation systems exist in the form of robots. One particular type of robot of which the applicants are aware is a robot manufactured by Zymark. These robots may be programmed to emulate all the movements a human being would make in doing a sample preparation process manually. Unfortunately, such systems are complicated and expensive and difficult to use because of the complexity of the mechanical machinery and control computers and software needed. Thus, a need has arisen for a control system for a sample preparation system which is flexible, programmable, easy to use, and relatively inexpensive to manufacture.

Summary of the Invention

In accordance with the teachings of the invention, there is provided a control system for a sample preparation system to fully automate the system and allow users to program their own sample preparation procedures or to use preprogrammed procedures. Further, the control system allows a user acting as a system manager to define the necessary sample preparation procedures for various types of samples likely to be encountered. Then the system manager may lock out users without system manager privileges to prevent them from altering the procedures while allowing such users to use the procedures programmed for them by the system manager.

The control system of the invention allows user interaction with the system at three levels. At the first level, users may only give the sample identification (in embodiments with no bar code reader), the sample weight, the user initials, the date and time, the lot number to run, and the method of sample preparation to be followed. These methods of sample preparation will have been programmed into nonvolatile memory before the control system is obtained by the user or will have been previously programmed in by the system manager.

The next level of user interaction is a high level language level. At this level, the user has various high level sample preparation system control commands at his disposal. Such commands include fill, mix, isolate, flush, dilute, inject, wash, etc. Each of these commands represents a predetermined sequence of events which will be caused by the control system to happen in the sample preparation system when the particular command is executed in the course of performing a sample preparation procedure. The user at this level may string a series of such high level commands together into a sample preparation procedure and give it a name. Upon selection of a high level command, the control system would prompt the programmer for any necessary variables or parameters, such as solvent selection, volumes, flow rates, mixing times, etc. Thereafter, by identifying the particular procedure the user wishes to run, the same sequences of events may be caused to occur in the sample preparation system of the invention. Some of the high level commands have parameters which are accessible to the user and may be set to accommodate the particular needs of the user. These parameters allow the user to control, for example, the amount of time a mixing step is carried out and the level of energy that is input to the mixer by the homogenizer.

The key to breaking up sample preparation procedures into a series of standard preparation steps, which can be chained or re-chained together in any useful sequence the user needs to accomplish his desired sample preparation procedure, is to design the hardware and software control logic to allow each standard preparation step and each programmed series of standard preparation steps to be completely independent of the preceding or following step or series of steps. For example, upon completion of a dilution sequence or cup wash cycle, the diluent or wash solvent from a prior dilution or rinse should not be left in the instrument connecting tubings or modules. If there is such leftover solvent etc., it may inadvertently contaminate the next dilution or wash with the wrong or an undesired solvent. If this undesired solvent could not be removed from all tubings and connections prior to the next step or sequence of steps, the next step would be restricted to using a solvent deemed compatible with the undesired solvent and thereby place undesired restrictions on the next step.

At the most detailed level, the control system according to the invention provides the user access to and programmability for elemental operations of the type that are combined into the sequences which make up each high level command. Such elemental operations control individual events in the system such as the opening and closing of a particular valve, the turning on of the homogenizer, setting of the power level of the homogenizer, etc. The user may program the system at this level by stringing names. These sequences may be thought of as user definable high level commands, or "macros." The user may string any number of macros together to form a procedure which may then be labelled and executed by referring to it by its name.

Brief Description of the Drawings

Figure 1 is block diagram of the hardware of the control system and the system electromechanical devices which are read and controlled by the control system.

Figure 2 is a schematic diagram of a typical sample preparation system which may be controlled by the control system of the invention.

Figure 3 is a schematic diagram of another embodiment of a sample preparation system which may be controlled using the control system of the invention.

Figure 4 is a flow diagram of the overall control flow of the control system software.

Figure 5 is a flow diagram of the various routines of the control system of the invention.

Figure 6 is a flow diagram of the create, modify and delete routine of the control system of the invention that allows a user to create new sequences of commands at either of two levels of detail and complexity.

Detailed Description of the Preferred Embodiment

Figure 1 is a block diagram of the electronics of the control system in accordance with the teachings of the invention. The control system is centered around a CPU 20 which could be a microprocessor, personal computer, minicomputer, or mainframe. Included within the CPU block is RAM memory for storing programs and data while the computer is running. Mass storage of data, programs, and other information such as data bases, macros, user defined parameters, user defined sample processing routines, etc., is performed by mass storage unit 22. This unit could be a disk drive, tape transport, bubble memory, or any other bulk storage device with sufficient access speed and storage capacity for the particular application involved. The user controls the computer 20 through a terminal comprised of keyboard 24 and any type of display 26.

The computer 20 is coupled to the various operating units in the sample preparation system by bus 28. This bus 28 is actually comprised of the address, data, and control signal lines of the computer 20. The bus is coupled to the ports for addresses, data, and control signals such as read/write, interrupt, ready, etc. on the various drivers and interfaces to the various functional elements of the system. A more complete description of the sample preparation system for which the control system is intended to be used with is given in the following U.S. patent applications:

"System for Preparation of Samples for Analysis" by Nau, Metzger, Orimm, Nohl, serial number 942,197, filed 12/16/86 and "Sample Preparation Chamber with Mixer/Grinder and Sample Aliquot Isolation" by Nau, Metzger, Grimm, Andre, and Nohl, serial number 942,198, filed 12/16/86, both of which are hereby incorporated by reference.

Because the sample preparation system is intended for use in applications where either the samples will be brought into the system in cups or other containers with bar codes thereon or pumped into the cup through a 6-way valve, a bar code reader 30 is provided. This allows sample identification data such as lot number and batch number or other types of information pertaining to the incoming samples to be read from bar codes on the sample containers. This information may then be read by the computer 20 and stored in the mass storage unit 22 for later correlation with the

test results for that group of samples. Bar code readers are known and systems for moving sample containers by bar code readers so that the bar codes may be read are also known.

In the preferred embodiment, a network interface controller 32 is provided to allow other computers and units on a network in the user facility such as terminals in the offices of scientists to offices, program the system or inquire as to the status of a particular sample preparation routine. Further, the users may have access to the data which resulted from a particular sample run. For the network interface, this user can have the sample data resulting from the assay of a particular lot of sample communicated directly into the data based in the other computer.

A sample loader 34 functions to mechanically load samples arriving in containers. The particular design of the sample loader is not critical to the invention. It may load sample from one or more containers brought in by the user such as a tray of test tubes into the sample preparation chamber. In such a system, the sample from each test tube would be loaded into the sample preparation chamber, homogenized, diluted, and pumped through the assay system. At some point in the process, the sample would be identified either by the user keying in the identification data or by the bar code reader 30 reading the bar code on the test tube. The analysis data from the assay would then be stored in the mass storage unit 22 along with the corresponding identification data. The sample loader would then load the sample from the next test tube into the sample preparation chamber, and the process would be completed for the sample from the next test tube. The design of such a sample loader is known and a commercially available unit which could be programmed to do the job would be the PRO/GROUP(tm) automatic assay machine available from Cetus Corporation in Emeryville, California. In alternative embodiments, the sample loader 34 could be any mechanical system which could take a cup like that used in the sample preparation chamber described in the patent applications incorporated by reference and attach it to the cap. Any mechanical arrangement that can load a cup from a tray, conveyor belt, or carousel of cups into mechanical sealing engagement with the cap of the sample preparation chamber described in the patent applications incorporated by reference will suffice. In some embodiments, this unit may be omitted altogether where sample is pumped in from a process stream or injected from a 6-way valve coupled to a sample vat. The design of suitable sample loaders which will suffice to practice this aspect of the invention is known.

There is also provided electronic scales 36 in the preferred embodiment. These provide the fa-

cility for weighing of solid samples or samples which are too viscous to pump into the sample preparation chamber where such samples are placed manually in the sample preparation chamber. The purpose of weighing such samples is to provide the user with an indication of the amount of sample that has been placed in the sample preparation chamber. This is important because the samples will later be diluted with solvents or diluent to a user defined concentration. In order to do this properly, the weight of sample in the sample preparation chamber prior to addition of the diluent must be known. The electronic scales also provide an RS232 or parallel interface to the computer 20 via the bus 28 so that the computer 20 may read the sample weight directly. The electronic scales may be eliminated in some embodiments. Without the electronic scales, if the user is dealing with a solid sample, the weight of sample placed in the sample preparation chamber must be keyed in by the user through the keyboard 24. A suitable electronic scale 36 would be the Mettler AE160 available from Mettler in Switzerland.

A pump interface 38 provides the facility for the computer 20 to control the reversible pump used in the sample preparation chamber. The pump motor may be a stepper motor or a D.C. servo motor with an optical or other type of encoder so that the pump interface circuit 38 can determine the position of the motor shaft at all times. Any type of motor with sufficient power and a system to positively control the pump shaft position or otherwise control the exact volume pumped will suffice. The pump interface obviously needs to be designed to interface between the particular type of pump motor and pump chosen and the particular type of computer 20 chosen.

Figure 2 shows one embodiment of a sample preparation system with which the control system of the invention may be used. In this embodiment of the sample preparation system, the details of the structure and operation of which are as described in the patent applications incorporated herein by reference, two manifolds 39 and 41 are used as central terminals in what amounts to a fluid switching multiplexer. Each manifold is coupled to various sources of material or various destinations in the system by a plurality of remotely controllable valves of which valves 43 and 45 are typical. These valves are typically solenoid operated or pneumatically operated under the control of the computer 20. The purpose of the valve interface 40 in Figure 1 is to electrically translate the address, data, and control signals on the bus 28 into the proper electrical or pneumatic control signals to cause the proper valve in the system to assume the proper state. Such interface circuits are well known, for either solenoid operated valves or pneumatically

operated valves. For example, in the case of solenoid operated valves, a motor controller chip can decode the address on the bus 28 and a data word indicating whether the valve is to be opened or closed along with an active write signal. All these signals define an action desired for a particular valve. The address specifies which valve is to be operated, and the active write signal indicates when the computer 20 is addressing a particular valve. The data word defines whether the valve is to be opened or closed or which of its multiple states to assume in the case of a multistate valve.

The motor controller chip then activates a particular output signal line coupled to a solenoid driver such as a relay or a triac in such a manner as to cause the desired change in the state of the addressed valve.

In the case of pneumatic valves, the address, data and control signals are decoded, as above, but the activated output signal from the motor controller chip is used to control a pneumatic pressure source to either apply pneumatic pressure or remove it from the particular valve addressed.

Figure 3 shows the preferred embodiment of the sample preparation system with which the control system in accordance with the teachings of the invention is used. The difference between this sample preparation system and the sample preparation system of Figure 2 is that the manifolds 39 and 41 and the associated valves such as valves 43 and 45 are replaced with two rotary, multistate valves 47 and 49. All other details of the system structure and operation are as described in the patent applications incorporated by reference herein. Each of these valves has a central input pipe, pipes 51 and 53 respectively, which is connected to only one of a plurality of output ports coupled to various sources of material or destinations in the system. A stepper motor or D.C. servo motor with optical encoder is used to drive the valve to its various states. In such an embodiment, the valve drivers 40 are the interface circuits needed to control the stepper motors or D.C. servo motors.

Integrated circuits for stepper motor control are commonly available. These circuits allow the computer 20 to send address and data words to the stepper motor controllers after enabling the chip with a proper chip select signal. The address signals indicate which of the two rotary valves is being addressed, and the data words indicate the desired state in which the rotary valve is to be placed. Typically, these integrated stepper motor controllers have a command set. Typical commands include commands to start and stop the controlled motor, commands to control the acceleration and deceleration profiles to use, commands to control the step number to which the controlled motor's shaft is to be moved, and commands to read the

particular step at which the controlled motor's shaft is currently resident. Such chips may be used to control the stepper motors used to drive the rotary valves 47 and 49. In the preferred embodiment of the sample preparation system, these rotary valves 47 and 49 are manufactured by Hamilton Company of Reno, Nevada.

A typical D.C. servo motor which could be used to drive the rotary valves 47 and 49 is manufactured by Galil Motion Control, Inc. of Mountain View, California under the model designation DMC 100. These servo motors have optical encoders which are used to provide feedback as to the shaft position to an interface board for the Galil motor plus motor controller chips for the other remotely controlled valves in the system.

The RS232 port interface 42 may be a simple commercially available UART. The analyzer 48 may be coupled to the computer 20 through the RS232 interface 42, or the network interface 32.

The mixer 55 in Figures 1 and 2 may be an ultrasonic mixer such as is made by Sonic and Materials of Danbury, Connecticut under the trademark VIBRA CELL. In alternative embodiments, a high speed homogenizer could be used such as are made by Brinkman (shroud with a high speed rotating shaft therein rotating at 28,000 RPM, thereby creating a high shear in the liquid and disintegrating particles therein). These units come with their own interfaces which may be used for the mixer interface 44. The basic control functions needed to control the mixer are the time of mixing and the power level which controls the amount of turbulence generated in the liquid. The mixer interface will be necessary electronics to interface with the mixer control circuit for the selected mixer. The details of how to interface the computer 20 to the interface circuits that come with the mixers will be apparent to those skilled in the art. A good reference for interfacing computers such as the computer 20 to control external instrumentalities is Libes and Garetz, Interfacing S-100/IEEE-696 Microcomputers, (Osborne/McGraw, Hill, 1981) which is hereby incorporated by reference. An auxiliary interface 46 is provided to allow the computer 20 to control external instrumentalities such as valves, solenoids, etc. which are outside the sample preparation system. Typically, this interface will be digital, programmable ports such as are commonly available in integrated circuit form where the characteristics of the ports may be set by the user.

Figure 4 is a high level functional diagram of the control program in the computer 20, which allows users to program and run their own sequences of events to be performed in the sample preparation system under control by the control system of the invention. The control program runs the user defined sequences by generating the

proper control signals to cause the desired sequence of events to occur in said sample preparation system.

At power up in some embodiments, the system will perform a self test to verify the integrity of the system prior to performing any operations. This is symbolized by block 50. Next, the system displays a user identification request/sample identification request screen as symbolized by block 52 (hereafter references to blocks will be understood to mean reference to those source code computer instructions organized as routines and subroutines in the control program which perform the function indicated in the block referred to). The purpose of block 52 is to supply query fields on the terminal or display 26 for the user to respond to by filling in the requested data via the keyboard 24. The requested data is to identify the user, to give various data items regarding the sample, to give the date and the time and to identify the sequence the user desires to run. The data items regarding the sample to be filled in may include the sample ID, the sample weight, and the lot number from which the sample came. The user identification number is used by the control system to determine the access privileges which the user has.

The control system has three levels of access. At the simple level, the user may only run sequences that have been previously programmed by the system manager. At the high level, users having access privileges at this level may program their own sequences of events using commands from a high level language command set. These commands represent predetermined building block functions which are necessary to perform sample preparation. Such building block functions include: mix, isolate known sample volume, flush the remaining liquid out of the sample preparation chamber, release the isolated sample volume, dilute the sample volume with a user defined volume of a user identified solvent, pump the diluted sample to the analyzer, etc. At the expert level, users having access to this level may program their own "macros" using system commands at a more detailed level than the high level commands identified above. These more detailed commands allow the user to control the system at a finer level of resolution. For example, a typical command may be "open valve #1" or "rotate multiport valve #2 to state #3." Each of the high level commands is comprised of a predetermined sequence of expert level commands.

The identification data entered by the user in block 52 via the keyboard 24 is stored on the mass storage device 22 in block 54. Next the system, in block 56, determines the access privileges of the user by comparing the user ID to the list of ID numbers supplied by the system manager for each

level of access.

Block 58 represents the step of displaying an option menu by which the user, by selecting an option, may express a request regarding what the user wishes the system to do or what the user desires to do with the system. Typical menu options include: start, status, method, directory, report, load, print, system, control, defaults, functions, and options. The meaning of these options will be explained more below.

After the user has entered his or her request via the keyboard 24, the control system verifies that the user has the access privilege necessary to perform the function requested in block 60. If so, the control system branches to the routine which performs the desired function or provides the facility requested by the user in block 62. If the user does not have the required access privilege, a message to that effect is displayed in block 64, and processing proceeds to block 58.

Referring to Figure 5 there shown a flow chart of the various routines which are available for selection by the user in Step 58 of Figure 4. The first routine, symbolized by block 64, is a routine which allows the user to create, modify, or delete an operation sequence. An operation sequence is a collection of commands which are executed by the central processing unit in order to generate control signals to control the electromechanical devices in the system. The control signals cause them to perform a physical sequence of events to process a sample where the sequence is defined by the particular sequence of commands in the program. The routine of block 64 allows the user to program his own sequences of commands at either of two levels of complexity. At a first level of complexity, the user may have access to a set of commands each of which represents a specified function that the system is capable of performing and each of which causes a predetermined sequence of events to occur in the proper order to cause the physical event symbolized by that command. The second level of complexity allows the user to have access to a set of commands which are very detailed. These commands each represent a single action or a very small group of actions that one or a very small group of electromechanical devices performs. Essentially, the commands at this second level are the component commands which are grouped together in a predetermined sequence to implement one of the commands on the first level. Essentially then, the commands on the first level are macros which are collections of commands on the second level but arranged in a predetermined sequence for each particular command on the first level.

Block 66 is a routine which allows the user to print a hard copy of a sequence which has been programmed by the user.

Block 68 is a routine which allows the user to load a predetermined sequence, i.e., a method of sample preparation which has been preprogrammed by the system manager. The system manager is a user which has access to all functions of the system. That is, the system manager can define the access privileges of all the other users on the system, and he may program preprogrammed sequences which are available for certain users who are not allowed to program their own sequences. Block 68 is the routine which the user calls when one of these preprogrammed sequences is to be loaded.

Block 70 is a routine which allows the user to print a directory of all the methods or sequences which are stored in the system and available for execution. Block 72 represents a routine which allows the user to start the selected sample preparation routine and which causes the CPU to begin generating the control signals which cause the physical actions to occur.

Block 74 represents a routine which displays the system status. Block 76 is a routine which allows the user to print the system status which is displayed in the routine of Block 74.

Block 78 is a routine which allows the user to change the system default parameters. Typically, each command on either the first or second programming level will have parameters or arguments associated therewith. These arguments are variable values which define the specific manner in which the command is to be performed. For example, a mix command may have as an argument the power level at which the mix is to be performed, the time duration of the mix, and the RPM that the mixer is to use.

The routine represented by block 80 allows the user to have access to the various valve and relay controls such that the user may open certain valves or close certain relays manually by causing the CPU to generate the proper command to cause the proper operation of the valve, relay or other electromechanical device.

Block 82 represents a routine which allows the system manager to create new system functions.

Block 84 is a routine which allows the user to print a report. Such reports may consist of reports of user activity, the sequences which have been run, the volume of activity for a particular sequence, and so on. Block 86 is a routine which allows the user to change the print parameters. This routine allows the format of the report to be set such as margins, spacing, headers, and other types of formatting commands common to database report routines.

Block 88 is a routine which displays for the user the system options which have been elected and which are operable.

Block 90 is a routine which allows the user to use the print mode of the system for various functions.

Block 92 is a routine which allows the system manager access to certain system functions.

Referring to Figure 6 there is shown a more detailed flow diagram of the create, modify and delete routine of block 67 in Figure 5. The first step when the user elects to program his own sequence is to inquire whether the user wishes to program on the first level or on the second level noted above.

10 The first level will be called the high level for purposes here, and this level will provide the user access to the macro commands. The second level will be called the expert level and grants the user access to the detailed commands which essentially allow the user to define each valve opening and closing and each operation of each motor or other electromechanical device individually. The levels are named the high level and the expert level for purposes of indicating the relative amounts of skill needed to program on these levels. Programming at the high level is similar to calling subroutines or macros on any computer. Programming on the expert level is similar to programming in source code and requires a some programming skill and a great deal of knowledge regarding the hardware aspects of the system being programmed.

15 The process of determining which level the user wishes to have access to is symbolized by step 94. This step also determines the user's access privilege by checking the user's identification code and comparing it to a table or other such database defined by the system manager which indicates which users have access to the high level command set and which users have access to the expert level programming command set.

20 If the user elects to program at the high level, the next step is symbolized by block 100. In this step, the user is prompted for a name for the sequence which he is about to program. After the sequence has been named, step 102 is performed wherein the user selects the first high level command which is to be executed in the sequence. In some embodiments, the list of high level commands from which the user may choose may be displayed and the user may simply choose a command by positioning the cursor on the proper command and pressing a select key. In other embodiments, the user may be required to know the high level commands and select the particular command desired by an acronym.

25 30 35 40 45 50 55 As noted above, most commands have certain parameters or arguments. Step 104 represents the process of prompting the user for parameter values for the command selected in step 102. Each command will have default parameters which are set by the user in step 78 of Figure 5. If the user wishes

to use the default parameters, he need do nothing in step 104. If however, the user wishes to define the specific manner in which the particular command is to be executed, then the parameters for that command may be adjusted in step 104.

After step 104 is performed, the control software causes the central processing unit to prompt the user to determine if the command just defined is the last command in the sequence. This step is symbolized by block 106 in Figure 6. If the user is done picking commands, the processing proceeds to step 108 where the method is stored in permanent storage such as on a floppy disk or hard disk. Processing then returns to the main menu symbolized by block 58 in Figure 4.

If the user is not finished programming, then processing proceeds from block 106 to block 110 where the user is prompted to select the next high level command in the sequence. Processing then proceeds to block 112 where the parameters for the command selected in block 110 are displayed and the user is prompted for new values for these parameters. If the user responds with new parameters, these are stored with the command as a permanent part of the sequence being programmed. After step 112 is performed, step 114 is performed to again to test for completion of programming. Step 114 represents the process of prompting the user to determine if the user is done programming. If he is, then processing continues at step 108 as described above to store the method. If the user is not done programming as determined in step 114, then processing returns to step 110 where the user is prompted to select the next command in the sequence.

Returning again for a moment to step 94 in Figure 6, if the user is determined to have no access to either the high level or expert level programming command sets, then step 94 vectors processing to a step 96 wherein a "no access privilege for selected level" message is displayed on the terminal. Thereafter, in step 98, processing is returned to the main menu of step 58 in Figure 4.

If the user selects the expert level for programming, a similar sequence of events occurs starting with step 116. There the user is prompted to name the sequence he is about to define. The next step, 118, prompts the user to select the first expert level command to be executed in the sequence. Then, in step 120, the user is prompted to select new parameters for the expert level command selected in step 118. Again, the expert level commands also have default values which may be altered by the user in step 120. Step 122 represents a test to determine if programming has been completed. If it has, then step 108 is performed as described above. If programming is not completed,

processing proceeds to step 124. There the user is prompted to select the next expert level command and define the parameters for that command.

Step 126 represents a test to determine whether the user is done programming. If he is, then step 108 is performed and control is returned to the main menu. If the user is not done programming, then control returns to step 124 where the user is prompted to select the next expert level command.

Appendix A is a listing of the source code for the preferred embodiment of the invention. This source code runs on an IBM PC running the Forth and DOS programs.

Although the invention has been described in terms of the preferred and alternative embodiments detailed herein, those skilled in the art will appreciate that many modifications may be made. All such modifications are intended to be included within the scope of the claims appended hereto.

Claims

1. A control system for an apparatus having a plurality of electromechanical devices controlled by said control system, said control system having a CPU (20) wherein the improvement comprises software means (Figures 4, 5, 6) for allowing a user to cause said CPU to run any of a plurality of fixed command sequences or to program one or more new sequences using commands at any of a plurality of complexity levels where at least one complexity level is populated by commands which are macro commands in the sense that each is a concatenations of commands from at least one other of said complexity levels.

2. The apparatus of claim 1 wherein said software means includes means (Figure 6) for allowing a user to program sequences at a first level with macro commands each of which causes a predetermined sequence of events to be performed by said electromechanical devices.

3. The apparatus of claim 2 wherein said software means is also for allowing said user to modify the parameters of each command from default parameters where said parameters characterize some physical characteristic of the sequence of physical events that will be caused by execution of said command by said CPU.

4. The apparatus of claim 3 wherein said software means includes means for allowing said user to program a new sequence of commands to cause said electromechanical devices to perform at least one physical event where the commands available to the user are more primitive than the commands on said first level in the sense that each command represents a predetermined sequence of events

which is less complex than the predetermined sequences of events caused by the commands at said first level.

5. The apparatus of claim 4 wherein said software means includes means for allowing each user to be identified by a code and further includes means for allowing at least one user to define the access privileges of all the other users and encode this access privilege data such that said software means can determine from said user identification code the access privileges each said user has.

6. The apparatus of claim 5 wherein said software means includes means to allow a first group of users to have access to and to run only said fixed sequences of commands and to allow a second group of users to run any of said fixed sequences of commands or to program a new sequence using only the commands at said first level and to allow a third group of users the ability to program a new sequence using commands at either of said first level or said second level or to run any of said fixed sequences.

7. A control system for an apparatus having a plurality of electromechanical devices comprising:

computer means for allowing a user to run fixed sequences of commands or sequences of commands the user programs himself and for generating control signals during the execution of these sequences which are coupled to said electromechanical devices and which cause these devices to perform the sequence of physical operations defined by the sequence being run; and

control means for said computer means for allowing said user to select and run any of one or more fixed sequences of operations or to program a new sequence at either of two levels of complexity.

8. The control system of claim 7 wherein said control means includes means to allow a user to program a new sequence using commands on a first level each of which represents a specific function of the system involving one or more physical actions of one or more of said electromechanical devices or to program a new sequence at a second level using commands each of which represents a single operation by a single electromechanical device.

9. The control system of claim 7 wherein said control means includes means to program a new sequence of operations using commands at either of a first level or commands at a second level wherein the commands at said first level each represent one physical operation by one electromechanical device and wherein the commands at said second level each represent a predetermined sequence of said commands at said first level.

10. The control system of claim 9 wherein said control means includes means to block access by certain users to commands for programming at either said first or second levels or both.

This block loads the entire Sample Preparation System.
It loads all other load blocks that make up the system.
A word called SP (or sp) will cause this block to be loaded.

PREP is the main entry point to the system, so after a power up,
just type "SP PREP" to load and run the system. Note that
SP will perform an 8 DRIVE before loading, so you don't have
to switch drives yourself.

SHADOW for configurations

SP loads the sample prep software. Type PREP to run.

(t") run time code for t", returns address of counted string.
t" compiles an inline string; will return it's address.
INVERT returns the ones complement of a value.
This is the title that shows up in .DRIVES

* *Xi* is the column offset to the left window edge (0..n).
Yi is the number of lines down from the top (0..n).
WWIDTH contains the # of chars across the window. (1..79)
WHEIGHT is the height of the window in lines (0..24)
C_ROW is the absolute screen line # of the cursor.
C_COL is the absolute screen column of the cursor.
 * *CRTSEG* is the screen memory segment address (88000)

REVERSE makes subsequent screen output reverse video.
 NORMAL restores output to normal video.

```

clear erases screen memory pointed to by *W* with count in reg. *I*

BLANKS takes a count and screen address and blanks *n* chars.

(cr) puts cursor in column 8 of the viewport window, and advances the cursor line #. If line # is beyond bottom of the window, it scrolls window contents up 1 line and puts cursor on last line. Returns cursor address in *W*.

?CR Tests cursor column position. If off right edge of window, it does a carriage return. *W* is preserved for (type).

```

8 \ Windows - Carriage return
1 CODE clear HERE DISPLAY LDA  8 ES LSG  ATTRIBUTE LDA

'expect' is an exact copy from screen 83 of level 4 listing.
It has to be defined here because the original is headerless,
and can't be found by WORD. (note the vert. bar in front of
CODE expect in the source listing: it compiles a headerless
definition)

```

8  \ Windows - expect
1 CODE expect ( n - n n n ) ASSEMBLER 32 & W MOV
2  1 1 SUB 1 2 MOV 8 POP 12 #8 8 CMP 8= IF
3      CNT U) DEC B 8< IF CNT U) INC B

15 \ Sample Prep Ver 8.1

```

This is the title that is used for program listings.

(CR) High level access to (cr). Performs carriage return.
(TAB) moves the cursor position to specified line and column.
Allows only valid window coordinates.
(TYPE) New vector for 'TYPE'.
(PAGE) vector for 'PAGE'. Clears window, homes cursor.
(EXPECT) is called from EXPECT in FORTH to get n chars and put
them to an address. PTR, CTR, CNT are setup by EXPECT and
used by 'expect'. Advances cursor position.

```

8  \ Windows - Screen output for FORTH
1 CODE (CR) ( --- ) ' (cr) CALL NEXT
2

13
14
15

```

These constants define the IBM characters for drawing boxes.

HWLINE draws a horizontal line the width of the window.
WSIDES draws the left and right window border.

4SIDES draws a box around the current screen window.

DRAWBOX clears the current window, draws a border around it,
and puts the viewport just inside the border.

```

8  \ Windows - Drawbox

```

WINDOW stores the window parameters, clears the window, and places the cursor at it's upper left corner.

BOX is the same as above, but draws a box around the specified window and makes the window 2 characters smaller in both height and width.

WORK The work window is the full width screen between the status header and the menu bar.

FULL uses the entire screen.

SELECTION is the small window on the right side used for selecting things.

WIDEDIR is used for full directory listings.

HELP SIZE is the help window.

```
8 \ Windows - Windowing
1
2 : WINDOW ( xl y1 w h --- )

15
```

These constants contain the addresses of the non-windowing output routines. Used when disconnecting the windowing functions, or writing directly to the screen.

TYPE types chars to the un-windowed screen. It duplicates the code found in scr 78 of Level 4 listing.
(1930 is address of (type))

TAB positions the cursor on the un-windowed screen.

EMIT prints a char to screen without using windows.

SPACE outputs a space directly to the screen.

SPACES sends n spaces.

CLINE clears the given full screen line.

EXPECT expects n chars to addr and echoes to full screen.

```
8 \ Windows - Full screen output
1 :TYPE ? CONSTANT [TYPE] 'EXPECT ? CONSTANT [EXPECT]
2 :PAGE ? CONSTANT [PAGE] 'TAB ? CONSTANT [TAB]
3 :CR ? CONSTANT [CR]

F# Current file number; directory index for this file.
 FPTR first block of file.
 BCT Number of blocks in file.
 EOF 0 = not end of file.
 UPDATED Flag indicates whether file was written to or not.
 DETAILS Controls directory printing: 0=short 1=long format
 LOADERR Not zero if a file was not found when loading.
 'BAT is the block number containing the block allocation table.
 MAXBLKS Number of blocks on disk that the file system uses.
 1STBLK The first useable block on an empty disk.
 BATSIZE is the number of bytes in the block allocation table.
 BAT_BUF is a buffer to hold the block allocation table when a
 file is open.

 15 : 8 PUSH NEXT

VBLK? aborts if the block number is invalid.
 FREEBLK finds the first unallocated block on the disk. It
 aborts if the disk is full.

EHBLK marks the given block as the end of file block in the
 BAT.
 ALLOCATE adds the given block to the end of the current file.

OF_FILE determines if the given block is already part of the
 current file; returns true if so.

8 \ File System - Block Allocation

OPEN? aborts if a file is already open.

-OPEN? aborts if a file is not open.

'LATEST returns a pointer to the most recently accessed block #.

LATEST returns the most recent block number (without update bit)

FLAGGED tests the update bit of LATEST.

?DRW returns true if the block belongs to drive C.

FUPDATE is used in place of UPDATE when writing to a file. It allocates a new block to the end of the file if the written block is not already part of the file.

rBLOCK reads the nth block relative to the beginning of the current file.

FBLOCK is used in place of BLOCK to access a file block.

```

6  \ File System - File Block Accessing
7 1 : OPEN? F# 0 1+ B> ABORT" file is open!" ;

14 : INITDIR MAXFILES 0 DO I 'ENTRY ENTRYLEN 0 FILL UPDATE LOOP
15

```

Modification date

File attributes

'ENTRY returns the address of the directory entry for file n.

INITDIR initializes a directory.

SCANDIR takes a pointer to a filename and searches for a match to that name in the directory. If found, it returns a valid file number, else it returns -1.

GETENTRY returns the next empty directory entry for a new file.

FOUND is used after SCANDIR to test for finding a filename.

FILEENTRY returns the address of the directory entry for the file in FB.

INITFILE copies the file pointer and block count into user variables and sets the indicator to "file not modified".

```

8  \ File System - Directory accessing
1 : SCANDIR ( 'name--- ft ) >R -I MAIFILES & DO
2  I 'ENTRY NMLEN J NMLEN-MATCH B= IF 2DROP I LEAVE

13
14
15

```

MAKEFILE constructs the directory entry for a new file. It allocates one block to the new file and sets the time and date of creation and modification. The directory entry will be written to the disk.

FCREATE Creates a new file if it doesn't already exist. The new file is opened for reading/writing. It returns 0 if successfull, 1 if the file already exists, and 2 if the directory is full.

```

8  \ File System - File creation
1 : MAKEFILE ( 'name f# - ) FREEBLK -1 OVER nBAT! SWAP 'ENTRY
2  DUP >R ENTRYLEN & FILL I BLK1 + ! I NMLEN MOVE

13  THEN
14  ELSE DROP 1
15  THEN ;

```

FOPEN opens an existing file for access. It sets FB to the file's directory index, and puts #BLKS into BCT and BLK1 into FPTA. Returns 0 if successfull, 1 if file does not exist.

FCLOSE Writes out the open file's new block count if the file has been modified, and updates the modification date and time.

FDELETE removes the given file from the directory (by putting a B in the first filename char), and releases it's blocks for other files to use.

```

8  \ File System - Programs access to files
1
2 : FOPEN ( 'name --- t ) OPEN? SCANDIR DUP FOUND IF F# !
3  GET_BAT INITFILE & ELSE DROP 1 THEN ;

Pointer to current Screen data structure.

'SCRN returns the address of the current screen data structure.

Fn# returns the address of selected function number.

Fn#? returns the currently selected function number.

Fn#! stores the current function number.

SCRN gets the address of the current screen ID number.

>FUNCT returns the address of an entry in the current screen table (pointed to by 'SCREEN') for the given function number.

FCHAR returns the command character for the given function number from the current screen.

```

NEWSCREEN switches the display to a new screen.

#SCRNS is incremented by each new screen definition and used as the screen ID. Contains the number of defined screens. The screen ID is used by HELP to display the right help screen. DEFSCRN is a compiler word that creates a Screen data structure. The structure consists of an index (0..7) of the currently selected function; a pointer to the previous screen; a pointer to a procedure to execute when this screen is selected and displayed; a unique screen ID number (screens are numbered sequentially from 1 to n as they are defined); and 8 function and 8 function entries, each containing three entries: the address of a function to execute, the address of a menu label displayer, and a command character that will execute the function.

```

8  \ Screen Support - Screen Data Structure Definition
1
2 : NEWSCREEN ( 'screen --- )
3  DUP 'SCREEN @ = NOT
4  IF DUP 'SCREEN ! \ point to new screen
5  .MENU \ print the new menu

15  LOOP DOES> ( --- ) NEWSCREEN ;

```

383

62

DO FUNC uses given index to fetch function pointer and executes it. >FUNC moves the highlighted selector left or right on the menu bar. +n is right, -n is left. +FUNC moves the selector to the right. The selector wraps around if in the rightmost position. -FUNC moves the selector to the left. The selector moves to the rightmost position if on position 0. SELECT executes the function pointed to by the current function index in the current Screen pointed to by 'SCREEN'. DESELECT exits the current menu and goes to the previously selected menu. CHAR>FN compares a given character to the function characters in the current screen and executes the function it matches.

```

8  \ Screen Support - Menu cell selection words

```

.HID prints the horizontal line for 1 cell.

.BOXTOP draws the top of one cell.

.BOXMID draws the middle line of a box.

.BOXBTM makes the bottom line of a box.

.TOPP draws 7 box tops.

.BOTH bottom

.DVRS saddles

.BAR prints the whole menu bar.

.FRAME builds the main screen outline: the status header and an empty menu bar.

.TOPP draws 7 box tops.

.BOTH bottom

.DVRS saddles

.BAR prints the whole menu bar.

8 \ Screen Support - ST/STP/PAUS/CONT and common Menu Labels

CMD is a function key routine that will accept a FORTH command from the keyboard and execute it, returning back to PREP. Characters are echoed on the inputline (line 25)

>CONTROL sends a command code and a command string pointer to the control task and waits for an acknowledgement message.

Displays an error message if not a positive ack.

HTHCTRL sends a command to the control task and redisplays the start/stop and pause/continue menu fields to show new command selections. (The commands depend on the current run status)

ST/STP is the start/stop menu command, either starts or stops a method.

PS/CNT pauses a running method or continues a paused method.

```

1 : >CONTROL ( a n -- ) TO CONTROL SEND_MSG
2 : FROM CONTROL MSGWAIT? ACK = NOT IF .ERROR ELSE DROP THEN
3 : .PAUSE ? &
4 : ST/STP ( - ) NULL START/STOP TO CONTROL SEND_MSG ;

11 : IF 0 CELLFL6 ! THEN .CELL 1 CELLFL6 ! ;
12 VARIABLE LASTSTATE
13 : NEWSTATE? ( - ) ;
14 : WHICHSTATE LASTSTATE ? = NOT MENU-ON? ? AND
15 : IF 0 SHO-CONTROL 1 SHO-CONTROL THEN ;

```

Use EMPTYCL for any undefined menu field.
HELPXT shows the help command field.

WHICHSTATE returns status of method 0=idle, 1=pause, 2=running

STRXTXT shows the START or STOP command depending on current run status.

PAUSEXT shows PAUSE, blank or CONTINUE menu command depending on run status.

```

8  \ Screen support - ST/STP/PAUS/CONT and common Menu Labels
1 : EMPTYCL .F"      .H"  ; \ empty cell
2

12   ELSE 1 CASE IF .F" PAUSE "
13     .H" Suspend procedure operation temporarily"
14   ELSE DROP .F" CONTINUE "
15     .H" Continue running procedure" THEN THEN ;

```

XRST is used after expect. Similar to RESET in FORTH which is un-findable.

INPUTXT gets a text string from the keyboard and returns the address of the counted string (count in first byte).

TXTPROMPT is given the address of a counted string to type as a user prompt on the inputline. The address of the input string is returned.

KEYPROMPT types a given prompt string on the message line and awaits a keystroke. It clears the prompt and returns the key.

YES? returns true if user typed a "Y" or "y", false otherwise.

.ERROR types an error string (counted) on the message line.
.MSG types a (counted) message string.

```

8  \ Screen Support - User Input / Output Words

```

GLEN? Returns true if the name length is 8.
ESC? Returns true if the escape key was the last char typed.
LEGAL? Returns true if all characters in name are legal.

FILENAME prompts the user with the given string, and processes his input. If return is typed with no chars, or the esc key is typed with any input, false and no input is returned to caller. If any non-legal characters are found, an error msg is displayed and user is re-prompted for input. A legal input will return the address of the counted input string and true.

1STHELP is the disk screen number of the first helpscreen.
 #HELPs is the number of defined help screens.
 HELPPARRAY contains help screen numbers for each major system screen. The 8th entry is reserved for general system help. Each of these help screens is a "chapter" heading, with further helpscreens available by using up or down arrow keys.
 SUBJECT points to one of the chapter screens in HELPPARRAY.
 HELPSCR is the current help screen #.
 BLK>SCR displays a given disk block as text.
 HELPSUBJ selects a help chapter based on given screen number.
 FINDHELP gets current screen and selects the right help chapter. +SUBJ advances +n chapters from current chapter and shows help. Used for paging through help subjects.
 +HSCR advances +n screens from current help screen. Used to "flip" pages of help screens.

This is the Function Editor that is used to edit user defined functions written in FORTH. It can also be used to edit any general text file, including parameter files and Method files.

This editor is based on the FORTH Inc. function key editor found on Screen 72 of the Level 3 Source disk. It has been modified to use the output windows of sample prep, and uses the prep file system for all disk I/O.

LAD is the only reference to disk I/O. It messages whenever of BLOCK, but deals only with file relative block numbers. LAD returns the address of the nth line of the current block, fetching it from the disk if necessary.

CLAD and any other word which modifies the text on the screen calls FUPDATE to mark the current disk block as modified. The FUPDATED block will ultimately be written out to the disk when that block's buffer needs to be reused by BUFFER, either by accessing other disk blocks, or by the file CLOSE operation when exiting the editor.

The directory and disk allocation information are updated when the file is closed.

```

EMPH_ON turns on both emphasized and double-strike modes.
 EMPH_OFF resumes normal printing.
 NXT_STATE points to the opposite print mode routine.
 CUR_ATR stores the current printing attribute.

NORM causes printing to be normal brightness. (the 256 is replaced by the address of BRIGHT below)
 BRIGHT causes printing to be emphasized and double struck.
 Given the next char's attribute, BRIGHTNESS will flip the printer into the proper print mode if the attribute is different from the previous char's.
 .CHR prints a character, replacing a null with a blank.
 ?CHAR fetches the char and it's attribute from the screen and prints it. Note that screen memory is in different segment

These message tokens are used to communicate between the user and the control tasks. Messages sent to the control task consist of a command token from this list, and a pointer to a string. The text string is used to pass filenames to the file load commands, and possibly to pass a FORTH command string to a (yet undefined) command interpreter. All other commands can send a NULL pointer.

Each command sent to the control task will be followed by a response token and a text string pointer indicating success or failure upon trying to execute the command. An ACK response will send a null pointer, which can be ignored; while a NACK response will send a pointer to an error message which should be presented to the user.

```

8 \ Task Support - Message Tokens, Load Block
1
2 \ Messages to control task:
3 1 CONSTANT START/STOP \ start or stop running
4 2 CONSTANT PAUS/CONT \ pause or continue running
5 3 CONSTANT 1STEP \ do just one step

12 \ 40 CONSTANT ACK \ positive acknowledgement
13 \ 80 CONSTANT NAK \ error!
14 116 123 THRU
15

```

Each "message" consists of a 8 bit token, and a 16 bit string pointer.

SEND_MSG waits until the message buffer is empty and puts the given message in the buffer. The message is taken by another task.

GET_MSG removes any message in the given message buffer and empties the buffer to allow another message to be placed.

MSGWAIT waits for a message to appear and then returns it.

The first byte of these message structures contains a message code (0 if no message waiting), bytes 1,2 are pointer to string.

TO_CONTROL contains a command for control if byte 0 not 0.

FROM_CONTROL contains the response to a command if byte 0 not 0.

```

```

These variables are used to maintain the system status information. For each item in the system that needs it's status displayed, there will be a variable that indicates it's current state that will be maintained by any operation that affects the item (such as turning a relay on); there will also be a variable maintained by either the status task (for status header information) or the status screen updating software that contains the currently displayed state of the item. In this way the status software can compare if the displayed state matches the current state, and update the display (and the display state variable) if they dont agree. This allows for a somewhat speedier updating loop, since only one or two items usually change for each pass through the status update loop.

RUN_STATUS Contains bits which indicate the state of the control task. The loading bits are used to recover from errors during a load operation. Normally, the load operation is completed and an acknowledgement is returned to the user task. But if an error occurs, the control task loop is exited and re-entered by the error handler. These bits are used to determine how to recover from the error and to send an appropriate error message.

BITMASK is a table of bit masks, indexed by a number from 0 to 7.

RLYBYTE# indicates which byte in the relay table we are currently indexing for status display.

RLYBYTE# takes a table address from the stack (either old or new status table) and returns the currently indexed status byte from this table.

BITMASK# returns a bitmask given a bit number (0-7) on the stack.

```

0 \ Status display - relay status updating - basic tools

IDLE? returns true if a method is not running.
BUSY? returns true if cycling from running to idle.
PAUSE? returns true if in pause state.
RUN? returns true if running, pausing, or stepping.
STEP? is true if in single step mode.
RSP sends a response (a message pointer and a token) to a command from the user task.
ACKRSP responds with ok if command was accepted.
NAKRSP is an error response, string is used for error message.
startrun will perform necessary processing to start a run.
endrun will do what is necessary to end a run.
notready responds with not ready error.
MTHOK? returns true if method exists and no load errors.
MTHDERR error if the method is not ok.

182

```

LAST-END contains a pointer to the address of "endaethod" in the last occurrence of END. If END is being compiled for the first time in a load, this pointer must be null.

ETHOD initializes the control task method parameters. It empties the dictionary space of the task, clears any outstanding status messages, resets LAST-END to 0, connects the tasks dictionary to the top of the main dictionary, clears the old method name.

```

0 \ Method Execution - initialization
1
2 VARIABLE LAST-END \ Points to "endaethod" in last END
3
4 : CMTHD
5  EMPTY @ MTHPTR !                                \ get rid of old method

12
13
14
15

```

METHOD Defining word. Compiles a new method and puts it's starting address into MTHPTR.

endaethod Run time code for END. Terminates method execution.

END Compiling word inserts "endaethod" as end of method definition and stops compiling the method definition. Since methods must be able to nest, "endaethod" must execute only once, at the end of the last method defined. The variable LAST-END is used to replace earlier compiled addresses of "endaethod" with EXIT, effectively converting all but the last occurrence of END into normal forth semicolons.

0 \ Method Execution - defining methods

```

1
2 : METHOD
3  HERE MTHPTR !
4  : LAST @ 2 CFA 2+ MTHPTR ! ;

The upper port of the PIA generates the address and control (read/write), while the lower port is for data in/out. These constants define the I/O addresses for the 6821 PIA chip on the Data-22 AC 2 adapter card.

- OUTDIR sets the PIA to all bits out for the given channel.
- INDIR sets the data direction to input.

RLYSOUT outputs the data value to the PAMUX port (8-2). (PAMUX is a parallel board connected to the PIA) RLYSIN gets the current state of all the relays.

529

RLY contains the relay # after RELAY is executed
PRT contains the PAMUX port address after RELAY (8-2).
MSK contains the bit mask to isolate the relay bit.

RLYUPDATE Given the new state (either on or off) for a relay, read in the current relay states for this group of 8, and set the new state for this relay. The current status for these relays is saved in RELAYS for status updating. Note that RELAY must be executed before ON or OFF.
RELAY converts a relay number (1 - 24) into a port # and it's bit position in the port.
ON and OFF turn just the relay selected by RELAY on or off.
INIT_RLYS sets all the relays to their user selected state. (defined by the bits in RLYDEFAULTS)

```

530

NAMED is used to give a relay a name: "4 RELAY NAMED METHANOL"
Later, use as: METHANOL RELAY ON
IS_OFF is used to define the state of the relay when "off". Allows a relay to be normally on rather than off.
Use: 4 RELAY 1 IS_OFF makes "on" the default for relay 4.
Combine the two definitions: 3 RELAY NAMED WATER 0 IS_OFF
DELAY waits a given number of milliseconds before returning.
Use it in user methods rather than FORTH's MS to allow recognizing the stop command. Quits back to main loop if stop

MS is redefined to be used as a units descriptor in a method.
Use: 5 MS DELAY or 10 SEC DELAY.
MIN waits for several minutes.

PI/O is the data input/output port for the pump controller.
 PSTS Status port for I/O.
 RCVRDY bit in PSTS is a 1 when data is available.
 INTRDY is a 1 when it is ok to transmit to the controller.
 PREADY is a 1 when the it is ok to send a pump command.
 P_STATUS? returns the I/O status flags.
 P_DATA? returns the data byte from the controller.
 P_DATA! writes a command byte to the controller.
 P_CTS? returns true if it's ok to transmit a command.
 P_RCVRDY? returns true if data waiting to be read.
 P_READY? returns true if the controller is ready.
 P_GETBYTE waits for a data byte and returns it.
 P_INFLUSH reads any remaining data bytes before returning.

PMPBUF is used to build pump command strings in. First byte is count. Also contains the characters returned by the controller after a command was sent. Look here for results.
 GBUF initializes the PMPBUF
 +BUF! stores the new character and increments the string count. Nonprinting chars are ignored.
 P_XMTWAIT flushes the input stream and waits until it's ok to transmit a new command to the controller.
 P_RESULT waits for the controller's command response (a ? or ?). A colon ":" signifies ok, while a "?" means error.
 >PUMP sends the string whose address and count are on the stack to the pump. Aborts if returned char is not ":".

TESTING WORD

(# Starts formatting a double number at the end of PMPBUF.
 # Ends formatting, string is in PMPBUF and addr, count on stack
 >STRNG converts a double number to a HEX format text string.

+CMDSTR builds a pump command string in PMPBUF given the address
 PCMD initializes command buffer and copies string to it.
 PPARM gets double number out of address and adds string to buffr
 PSEND ends a command string with a ";" and sends it to the pump.

15 : REVERSE ( n --- ) 0 PDIR ! ;

```

538

217

SENDPARM gets the address and length of command string, and address of a double variable and generates a complete pump command. Command looks like: "SP10000". Refer to pump manual.

These commands all set pump controller variables.

SETALL sends the necessary variables to the pump.

8 \ Pump - Send Pump Parameters

```

1 : SENDPARM ( ap ac n --- ) PCMD PPARM PSEND ;

```

539

218

TELLPMP Sends a 2 character pump command.

PABORT is an emergency stop, turns the motor off immediately.

P_WAIT waits for operation complete, aborts if stop command.

PSTART starts a pump operation. Controls pump status flag.

PRESET causes controller to use it's default parameters.

PREVERSE pumps in reverse direction.

PFORWARD pumps in forward direction.

PDECIMAL Controller interprets numbers in decimal format.

PHEX Controller interprets numbers in Hex format (default).

PSERVO Puts controller in servo mode.

PDIRECTION sets the pump direction based on contents of DIRECTION.

PUMP sends an entire set of commands to start up the pump using the current pump parameters.

INIT_PUMP does the pump initialization.

```

This code is used to manipulate the parity of characters that are send to and received from the Hamilton controller. The communication protocol for the device requires that the addressing character be send as an odd parity, while all other characters must be sent as even parity characters. The alternate way of manipulating the parity by programming the UART is not practical for reasons of speed and synchronization.

```

RBUFF is a wrap around receiving buffer, whose length may be modified through changing RBUFF-SIZE. This buffer is filled by the COLLECT loop, running under task REMOTE.

RDPTR, WRPTR, and RCOUNT are used to maintain RBUFF. The first two are a read pointer and a write pointer into the buffer, and the last one is a count of characters received.

SBUFF is a small buffer for storing the characters that we send to the controller.

```

8
9
10
11
12
13
14
15

```

548

227

RBUFF+ is an addition word that returns a 'wrapped around' result, corresponding to the size of RBUFF.

RBUFF? gets the nth character of the most recent unread portion of the receive buffer.

RBUFF-CLEAR clears the first n characters of the most recent unread portion of the receive buffer.

ECHO? returns true if exactly n characters have been received at the serial port.

```

RV-# contains the current valve number

RV-STAT-TABLE contains pairs of status variables (old and new) for the four valves

RV-STAT returns the address of the new status variable for the currently selected valve (RV-#)

RV-DIRECTION takes a position number and returns a direction character (+ or -) for the Hamilton command string. The valve will rotate either one position counter clockwise or one or two positions clockwise. The first rotation of the valve is always clockwise.

```

These are the top level commands for the hamilton rotary valve controller. RVALVE selects a current valve as in the phrase 3 RVALVE. POSITION selects a valve position corresponding to the position numbers that appear on the top of the valve assembly, and sends the valve to that position. PORT allows the user to use conventional numbers for valve positions, namely -1- for up, -2- for right, -3- for down, and -4- for left. The following are examples of usage:

1 RVALVE 3 PORT = 1 RVALVE 7 POSITION
2 RVALVE 4 PORT = 2 RVALVE 16 POSITION

15

```

Read the year and set the FORTH system year.
Read the time and set FORTH's clock.

The MONTHS array is used to convert the current day and month into FORTH's internal date format. Refer to screens 30 and 31 in the Level 3 listing.

SETDATE gets the current day and month from the battery clock on the AST card and sets FORTH's date.

Initialize FORTH's day, date, and time from the AST card clock.

Sample prep

These definitions are for the AST SixPac Plus card with the Ricoh RP5C15 clock chip.

CLK2 reads a value from one of the AST card clock registers.

Read the Year

Month

Day

Hour

Minute

Second from the Battery clock.

'QUIT is a user variable in each task that contains the address to execute when an error occurs.

The error handler for each task should process the error if possible; saving state information for debugging (like SCR, >IN, etc); and re-enter the main task loop to allow recovery. This will prevent system lockups on errors.

Initialized to QUIT for now (normal FORTH system error response).

ERRORS is executed when ABORT is called. It gets the error routine address for this task and starts interpreting it.

Modify the ABORT routine in FORTH to vector to ERRORS instead of QUIT.

***** SYSTEM NOTE: If the FORTH system is ever recompiled, the ABORT routine itself should be modified to implement the above behaviour. It is not good practice to poke in code changes after the system is up and running.

8 \ System Error Handling

```

(edit) is the editor command interpreting loop. It gets key strokes, updates the cursor position, and executes function keys until the exit flag is set

>EDIT throws 2 return addresses away off the stack and reenters the editing loop.

can't do an empty-buffers without loosing directory and BAT
information too. Solution is to Copy the existing file
to a "xxxx.BAK" file, edit that one, and just delete it if
the user wants to forget any changes.

*2 (the plus function key) is supposed to flip between a screen
and it's shadow or documentation block. In FORTH, the
convention is to have documentation blocks a fixed offset
above source blocks (typically 1 drive higher so that source
and documentation are on seperate drives). How should
documentation blocks be handled? Perhaps a different file type
where the source code would be in "xyzabc.txt" and it's shadow
would be in "xyzabc.doc". This means we need multiple open
files, which the file system doesn't currently support.

```

```

EDMENU displays the editing commands in the selection window.

FEDIT is the main entry point to the editor. It tries to open
an existing file and if it is not found, it prompts before
creating a new file.

```

238

MESSAGE compiles a message and makes it the method message at execution time.

MESSAGE-OFF turns off the method message, if any.

FMESSAGE compiles a message and makes it the function message at execution time.

FMESSAGE-OFF turns off the function message, if any.

```

RV-NAME-TBL is a table of pointers to strings that contain the names for the rotary valve positions.

CD-NAME-TBL is a table of pointers to strings that contain the names for the contact device positions.

These load commands compile new strings and put their addresses in the given table.

```
8 \ System configuration tables and load screen
1
2 241 LOAD  \ String table generation words
3
4 CREATE RV-NAME-TBL  32 ALLOT
5 CREATE CD-NAME-TBL  96 ALLOT

12
13
14
15
```

562

IS-PTR is a pointer to the location at which we compile the string's address. It serves as an index into a table.

IS-LEN is the required length of the strings that are being compiled.

CONFIGURE and CHARACTER set IS-PTR and IS-LEN in a clean syntax. See the last note in this block.

CSTRING compiles a string and places its address into a table, advancing IS-PTR for the next string.

STRINGS compiles the required number of strings.

The syntax of usage is: CONFIGURE n * CHARACTER STRINGS. The address of the table is given on the stack before starting.

8 <<< HELP FOR STATUS SCREEN >>>
1
2 This is the System Status Screen. The display shows the
3 current state of each system element.
4
5 F1 is the Start/Stop key. Use it to control method operation.
6 F2 is the Pause/Continue key. Use it to suspend a run.
7 F3 allows a direct command to be entered (for debugging only).
8 F4 allows exiting back to the FORTH system.
9 NUM LOCK causes the current screen display to be copied to the
10 printer.
11 <- ->. Keys move the command selector across the menu.
12 + Causes the currently selected command to be executed
13 - or ESC Exits the current Screen.
14 Type the first character of the command name to execute it
